The most convenient two units to use in thinking of radio wave frequency (RF) and wavelength are megahertz (MHz; mega means 1 million) and meters (m). The equation describing the relationship is much simpler when you use MHz and m: $f = 300 / \lambda$ in m and $\lambda = 300 / f$ in MHz

Easy to apply modulation at a low power stage of the transmitter: Another advantage of frequency modulation is associated with the transmitters. It is possible to apply the modulation to a low power stage of the transmitter, and it is not necessary to use a linear form of amplification to increase the power level of the signal to its final value.

What is FM, Frequency Modulation » Electronics Notes

Frequency modulation is the encoding of information in a carrier wave by varying the instantaneous frequency of the wave. The technology is used in telecommunications, radio broadcasting, signal processing, and computing. In analog frequency modulation, such as radio broadcasting, of an audio signal representing voice or music, the instantaneous frequency deviation, i.e. the difference between the frequency of the carrier and its center frequency, has a functional relation to the modulating sign

Frequency modulation - Wikipedia

Thereafter, in a radio communication environment, we perform the task of radio signal modulation to transfer the amplitude and frequency variant baseband signal to a radio frequency electrical waveform called the Carrier. The carrier is typically at a much higher frequency than the baseband signal. However, they are both forms of electrical energy.

The Math. We saw in the previous page that frequency modulation is achieved by adding the integral of the baseband signal to the argument of a sine or cosine function (where the sine or cosine function represents the carrier): $x_{FM}(t) = \sin(2\pi f_c t + 2\pi k_f \int_{-\infty}^t x_{BB}(t) dt)$ $x_{FM}(t) = \sin. ?.$
